## Session 1: Basics, writing scripts, read/write data

## Data types

## Assigning values with destinctive data types to variables

In order to handle your data right it is very essential to know which type your data is, as different data types have different properties and allow different operations. There are various different data types available in R (e.g. there are several different date formats in R that behave slightly different and are explicitly required for some functions). As a start in R the most essential types to know are:

• Logical These only have two states either TRUE or FALSE:

```
# Logical variables
x_true <- TRUE
x_false <- FALSE</pre>
```

• Numeric These are integer or floating point (double) numbers:

```
# Numeric variables (either integer or double (floating point number)):
x_int <- 1
# if you want to set a variable explicitly to integer:
x_int <- 1L
x_double <- 1.54</pre>
```

• Character Text strings of any length. Indicated by apostrophs:

```
# Character variables
x_chr <- "Text"
y_chr <- "Text 1"
z_chr <- "12.426"</pre>
```

• Factor Very critical data type. It is often mistaken with character or numeric. When it is not explicitly needed in any function (e.g. ANOVA requires factors for the model) factors should be avoided (see data.frames). These are used for categorical data and can only take defined values ("labels") predefined in e.g. a vector. The example below should illustrate the difference between a character vector and the case when the character vector is converted to a factor vector:

```
x_chr <- c("R1", "R2", "R4", "R1", "R1", "R2")
x_fct <- as.factor(x_chr)
x_chr

## [1] "R1" "R2" "R4" "R1" "R1" "R2"

x_fct

## [1] R1 R2 R4 R1 R1 R2
## Levels: R1 R2 R4</pre>
```

• Date formats As mentioned above there are several date formats available. Here the standard date format is mentioned, as it is the easiest to handle in the beginning. The standard date structure that is automatically recognized by the as.Date() function is YYYY-MM-DD. If the date structure in your data differs, you as a user have to give the function the date format as well. This is illustrated in the examples below:

```
x_Date <- as.Date("2010-12-25")
y_Date <- as.Date("2010-08-05")

# Examples for dates if the date format is not the standard format If the date
# (e.g. in your data) is not given in the standard format as in the two examples
# above, the user has to tell the function as.Date in which format the date is
# given. See the two examples below:
date_1 <- as.Date("25.12.2010", "%d.%m.%Y")

date_chr <- "12:25 05.08.10"
date_2 <- as.Date(date_chr, "%H:%M %d.%m.%y")</pre>
```
